ABSTRACT. The male genitalia of Dichomeris illusio Hodges and D. minensis Hodges are described and illustrated. New distribution records for these species are provided.

Additional key words: genitalia, illustration, Dichomeris illusio, Dichomeris minensis, Dichomeridinae, Black Belt Prairie

Dichomeris Hübner, one of the largest genera of Gelechiidae in the world, includes 74 species in America north of Mexico (Hodges 1986). The genus includes 58 species that have been recorded from states and provinces east of the Great Plains; of them, 22 species have ranges extending into the Great Plains and the southwestern United States (Hodges 1986). According to Hodges (1986), only 12 species are known from the southwestern United States. During recent years 39 species of Dichomeris have been collected in Alabama and Mississippi, and specimens are deposited in the Mississippi Entomological Museum.

Dichomeris is characterized anatomically by the abdominal segment II having a pair of venulae with anterior apodemes not developed, the forewing having abdominal segment II having a pair of venulae with in the Mississippi Entomological Museum. Alabama and Mississippi, and specimens are deposited in the southwestern United States. During recent years 39 species of Dichomeris have been collected in Alabama and Mississippi, and specimens are deposited in the Mississippi Entomological Museum

Dichomeris illusio Hodges and D. minensis Hodges are described and illustrated. New distribution records for these species are based on material in the Mississippi Entomological Museum at Mississippi State University. Photographs of the imagos and female genitalia of these species may be found in Hodges (1986) and at the following website: http://www.msstate.edu/org/mississippientmuseum/Researchtaxapages/Gelechiidahome.html

Dichomeris illusio Hodges

(Figs. 1 and 2)

Thorax: Forewing pattern similar to female; male without scale tuft on anepisternum.

Male genitalia: Valva approximately 1.1× length of tegumen + uncus, abruptly widened near midlength, apical third densely setose on dorsal half; vinculum subequal in length to tegumen + uncus, with a pair of medially projecting lobes arising from near base, lobes sparsely setose apically, saccal region sclerotized and broadly rounded (almost quadrato) ventrally, lobes of junta arising from common base, broadly bifid, dentate, and sparsely setose apically, aedeagus free from junta, lateral areas without sclerotized lobes, moderately sclerotized, with more heavily sclerotized plate ventromedially, cornutus broad basally; gnathos with relatively short hook; uncus with apical margin rounded, lateral margins slightly excavated beyond base, dorsal surface with sparse, slender setae, ventral surface with sparse setae, that are stout basally and taper to acute apices.

Notes: Hodges (1986) distinguished D. illusio from the superficially similar D. bolize Hodges by the distinctive female genitalia. The male genitalia of D. illusio differ from those of D. bolize and other Dichomeris species in having juxtal lobes with bifid and dentate apices. The valvae of D. illusio differ from those of D. bolize and related species in being abruptly widened near midlength. The characters of the male
genitalia of *D. illusio* confirm its previous placement by Hodges (1986) in the *D. setosella* group and include the following: vinculum sclerotized in saccal region; aedeagus free, with strong cornutus; uncus well developed, and posterior margin rounded or slightly angled distolaterally.

**Dichomeris mimesis** Hodges

(Figs. 3 and 4)

**Thorax**: Forewing pattern similar to female; male without scale tuft on anepisternum.

**Male genitalia**: Valva approximately 1.1\(\times\) length of tegumen + uncus, slightly narrowed apically, apical one-fourth of inner surface densely setose; vinculum subequal in length to tegumen + uncus, sinuous ventrally, with a pair of medially projecting, wide lobes arising from near base, lobes moderately setose apically, saccal region sclerotized and slightly rounded; lobes of juxta connected basally on ventral margin of saccus, almost symmetrical, irregularly dentate laterally; aedeagus free from juxta, lateral areas without sclerotized lobes, with more heavily sclerotized plate ventromedially, apex with sclerotized, tapered plate on lateral surface, cornutus broad basally; uncus with apical margin rounded, setae on dorsal surface sparse, slender, setae on ventral surface stout basally, narrowed and tapered near their midlengths.

**Notes**: All specimens of this species were collected in remnants of the Black Belt Prairie, where several species of insects are disjunct from western states (Brown 2003). The forewing pattern of *D. mimesis* is similar to that of *D. bolize* Hodges, *D. illusio* Hodges, *D. legnotoa* Hodges, and *D. pelta* Hodges. Hodges (1986) stated that "it is possible that the combination of the dark costal margin of the forewing and the shape of the posterior margin of the yellow of the forewing is diagnostic for *mimesis*, but too few specimens are known to be certain." The additional specimens from Mississippi and Alabama have a dark costal margin and two notches on the posterior margin of the yellow band of the forewing, not three as indicated in the key of Hodges (1986); however, this notched margin is much more irregular on the distal half than that in related species as indicated in Hodges' key. The male genitalia of *D. mimesis* differ from superficially similar species by the more narrowly rounded uncus, as compared to the broadly rounded uncus in related species, and by the form of the aedeagus and its sclerotized plate at the apex. The characters of the male genitalia of *D. mimesis* confirm its previous placement in the *setosella* group.

**Acknowledgements**

We thank Dr. Ronald W. Hodges for his assistance in the examination of specimens and confirmation of identities. We thank the staffs of Bon Secour National Wildlife Refuge and Noxubee National Wildlife Refuge for allowing collection of specimens on land under their management. Support for collection of specimens and this research was provided by National Science Foundation grants BSR-9024810, DEB-9200856, and DEB-0416078 and by Mississippi Agricultural and Forestry Experiment Station project MIS-6538.
